

China Steel Strategy Analytics Portfolio

Market monitor · cost bridge · 2025–2030 scenarios ·
competitor & policy intelligence

The 60-second strategy read

104

weekly observations

18

scenario-year outputs

6

major China producers

1

auditable model

**One data spine connects recurring updates to medium-term decisions:
market → cost → margin → scenario → action.**

Latest modeled conditions show a positive but exposed margin buffer

Synthetic weekly data, latest point in the generated series

\$533/t

HRC price

\$333/t

blended cash cost

\$166/t

HRC margin

3.23 Mt

weekly exports

Implication: raw-material volatility and product mix can move earnings faster than modest volume changes.

A recurring market update should connect price, inputs and margin

- Price alone is not the decision metric.
- Use raw-material and cost bridges to explain spread movement.
- Escalate unusual gaps after QC, not before.

The cash-cost bridge makes route exposure explicit

Illustrative USD/t; editable signed bridge bars, not proprietary think-cell objects

Model design

- BF-BOF: ore + coal + conversion
- EAF: scrap + electricity proxy
- Blended route mix stays visible

Scenario logic separates assumptions from conclusions

Lever	Downside	Base	Upside
Demand CAGR	-2.5%	-1.0%	+0.5%
Supply CAGR	-1.2%	-0.8%	-0.4%
Price elasticity	0.55	0.65	0.75
Cost inflation	1.0%	1.5%	2.0%
2030 EAF share	20%	23%	26%

Audit trail

Base case: capacity discipline partly offsets softer demand

2030 model output

932 Mt demand

956 Mt supply

\$66/t margin

Margin outcomes are more sensitive than volume headlines

- Use scenarios to expose the decision range—not claim a forecast.
- Watch cost inflation, elasticity and EAF pathway alongside demand.
- Refresh assumptions when policy or raw-material regimes change.

China's producer landscape is concentrated at the top

Public 2024 crude steel production; group scope affects comparability

Screen beyond scale

- Product mix
- Regional footprint
- Cost-curve position
- Decarbonization pathway

Policy belongs inside the model, not in an appendix

Capacity

Replacement and compliance can slow effective supply growth.

Process

EAF and low-carbon routes change input exposure and capex.

Mix

Product upgrading can support value even if tonnes soften.

Data

Digital monitoring improves policy and operating visibility.

A practical operating cadence turns analysis into action

Cadence	Core output	Decision
Weekly	Price, inputs, output, demand, spread	Investigate exceptions
Monthly	Trend, variance, competitor/policy updates	Refresh view and priorities
Quarterly	Scenario and sensitivity refresh	Reallocate research effort
Event-driven	Policy or commodity shock note	Rebase assumptions

Recommendation: monitor the spread drivers, then update the scenario

- Lead recurring updates with margin and supply-demand balance, not price alone.
- Treat capacity discipline and decarbonization as model inputs with explicit assumption owners.
- Use competitor output as a scale screen; layer mix, geography and cost position before concluding.
- Maintain an evidence log that separates public facts from synthetic portfolio outputs.

This deck contains editable native charts and tables. It does not contain proprietary think-cell objects.
